Abstract

Common Crawl is a considerably large, heterogeneous multilingual corpus comprised of crawled documents from the internet, surpassing the 20TB of data and distributed as a set of more than 50 thousand plain text files where each contains many documents written in a wide variety of languages. Even though each document has a metadata block associated to it, this data lacks any information about the language in which each document is written, making it extremely difficult to use Common Crawl for monolingual applications. We propose a general, highly parallel, multithreaded pipeline to clean and classify Common Crawl by language; we specifically design it so that it runs efficiently on medium to low resource infrastructures where I/O speeds are the main constraint. We develop the pipeline so that it can be easily reapplied to any kind of heterogeneous corpus and so that it can be parameterised to a wide range of infrastructures. We also distribute a 6.3 TB version of Common Crawl, filtered, classified by language, shuffled at line level in order to avoid copyright issues, and ready to be used for NLP applications.

1 Introduction

In recent years neural methods for Natural Language Processing (NLP) have consistently and repeatedly improved the state-of-the-art in a wide variety of NLP tasks such as: parsing, POStagging, named entity recognition, machine translation, text classification and reading comprehension among others. Probably the main contributing factor in this steady improvement for NLP models is the raise in usage of *transfer learning* techniques in the field. These methods normally consists in taking a pre-trained model and reusing it, with little to no retraining, to solve a different task from the original one it was intended to solve;

in other words, one *transfers* the *knowledge* from one task to another.

Most of the transfer learning done in NLP nowadays is done in an unsupervised manner, that is, it normally consist of a language model that is fed unannotated plain text in a particular language; so that it extracts or learns the basic features and patterns of the given language, the model is subsequently used on top of an specialised architecture designed to tackle a particular NLP task. Probably the best known example of this type of model are word embeddings which consist of real-valued vector representations that are trained for each word on a given corpus. Some notorious examples of word embeddings are word2vec (Mikolov et al., 2013), GloVe (Pennington et al., 2014) and fast-Text (Mikolov et al., 2018). All these models are context-free, meaning that a given word has one single vector representation that is independent of context, thus for a polysemous word like Washington, one would have one single representation that is reused for the city, the state and the US presi-

In order to overcome the problem of polysemy, contextual models have recently appeared. Most notably ELMo (Peters et al., 2018) which produces deep contextualised word representations out of the internal states of a deep bidirectional language model in order to model word use and how the usage varies across linguistic contexts. ELMo still needs to be used alongside an specialised architecture for each given downstream task, but newer architectures that can be fine-tuned have also appear; for these, the model is first fed unannotated data, and then it is fine-tuned with annotated data to a particular downstream task without relying in any other architecture. The most remarkable examples of this type of model are GPT-1, GPT-2 (Radford et al., 2018, 2019), BERT (Devlin et al., 2018) and XLNet (Yang et al., 2019); the latter being the current state-of-the-art for multiple downstream tasks. All of these models are different arrangements of the Transformer architecture (Vaswani et al., 2017) trained with different datasets; except for XLNet which is an instance of the Transformer-XL (Dai et al., 2019)

Even though these models have clear advantages, their main drawback is the amount of data that is needed to train them in order to obtain a functional and efficient model. For the first English version of word2vec, Mikolov et al. (2013) used a one billion words dataset consisting of news various news articles. Later Al-Rfou et al. (2013) and then Bojanowski et al. (2017) used the plain text from Wikipedia to train distributions of word2vec and fastText respectively, for languages other than English. Now, the problem of obtaining large quantities of data aggravates even more for contextual models, as they normally need multiple instances of a given word in order to capture all its different uses and in order to avoid overfitting due to the large quantity of hyperparameters that these models have; Peters et al. (2018) for example use a 5.5 billion token¹ data set comprised of crawled news articles plus the English Wikipedia in order to train ELMo, Devlin et al. (2018) use a 3.3 Billion words² corpus made by merging the English Wikipedia with the BooksCorpus (Zhu et al., 2015), and Radford et al. (2019) use a 40GB English corpus created by scraping outbound links from Reddit³

While Wikipedia is freely available, and multiple pipelines exist⁴⁵ to extract plain text from it. Some of the bigger corpora mentioned above are not made available by the authors either due to copyright issues or probably because of the infrastructure needed to serve and distribute such big corpora. Moreover the bast majority of both these models and the corpora they are trained with are in English, meaning that the availability of high quality NLP for other languages, specially for low-resource languages, is rather limited.

To address this problem, we choose Common Crawl⁶ which is a 20TB mutilingual free to use corpus composed of Crawled websites from the

internet and we propose a highly parallel multithreaded asynchronous pipeline that applies wellknown concurrency patterns, to clean and classify by language the whole Common Crawl corpus to a point where it is usable for Machine Learning and in particular neural NLP applications. We optimise the pipeline so that the process can be completed in a sensible amount of time even in infrastructures where I/O speeds become the main bottleneck.

Knowing that even running our pipeline will not always be feasible, we also commit to publishing our own version of a classified by language, filtered and ready to use Common Crawl corpus upon publication of this article. We will set up an easy to use interface so that people can download a manageable amount of data on a desired target language.

2 Related Work

Common Crawl has already been successfully used to train language models, even multilingual ones. The most notable example in probably fast-Text which was first trained for English using Common Crawl (Mikolov et al., 2018) and then for other 157 different languages (Grave et al., 2018). In fact Grave et al. (2018) proposed a pipeline to filter, clean and classify their fastText multilingual word embeddings, which we shall call the "fastText pre-processing pipeline". They used the fastText linear classifier (Joulin et al., 2016, 2017) to classify each line of Common Crawl by language, and downloaded the initial corpus and schedule the I/O using some simple Bash scripts. Their solution however, proved to be a synchronous blocking pipeline that works well on infrastructures having the necessary hardware to assure high I/O speeds even when storing tens of terabytes of data at a time; but that downscale poorly to medium-low resource infrastructures that rely on more traditional cost-effective electromechanical mediums in order to store this amount of data.

Concerning contextual models, Baevski et al. (2019) trained a BERT-like bi-directional Transformer for English using Common Crawl; they followed the "fastText pre-processing pipeline" but they removed all copies of Wikipedia inside Common Crawl. They also trained their model using News Crawl (Bojar et al., 2018) and using Wikipedia + BooksCorpus, they compared three

wikiextractor

⁵https://github.com/hghodrati/wikifil

⁶http://commoncrawl.org/

models and showed that Common Crawl gives the best performance out of the three corpora.

The XLNet model was trained for English by joining the BookCorpus, English Wikipedia, Giga5 (Parker et al., 2011), ClueWeb 2012-B (Callan et al., 2009) and Common Crawl. Particularly for Common Crawl, (Yang et al., 2019) say they use "heuristics to aggressively filter out short or low-quality articles" from Common Crawl, however they don't give any detail whatsoever about these "heuristics" nor about the pipeline they use to classify and extract the English part of Common Crawl.

It is important to note that none of these projects distributed their classified, filtered and cleaned versions of Common Crawl; making it difficult in general to faithfully reproduce their results.

3 Common Crawl

Common Crawl is a non-profit fundation which produces and maintains an open repository of web crawled data that is both accesible and analyzable. Common Crawl's complete web archive consists of petabytes of data collected over 8 years of web crawling. The repository contains raw web page HTML data (WARC files), metdata extracts (WAT files) and plain text extracts (WET files). The organisation's crawlers has always respected nofollow and robots.txt policies.

Each monthly Common Crawl snapshot is in itself a massive multilingual corpus, where every single file contains data coming from multiple web pages written in a large variety of languages and covering all possible types of topics. Thus, in order to effectively use this corpus for the previously mentioned Natural Language Processing and Machine Learning applications, one has first to extract, filter, clean and classify the data in the snapshot by language.

For our purposes we use the WET files which contain the extracted plain texts from the websites mostly converted to UTF-8, as well as headers containing the metatada of each crawled document, each WET file comes compressed in gzip format¹⁰ is stored on Amazon Web Services. We use the November 2018 snapshot which surpasses the 20TB of uncompressed data and contains more

than 50 thousand plain text files where each file consists of the plain text form multiple websites along its metadata header. From now on, when we mention the "Common Crawl" corpus we refer to this particular November 2018 snapshot.

4 fastText's Pipeline

In order to download, extract, filter, clean and classify Common Crawl we base ourselves on the "fastText pre-processing pipeline" used by Grave et al. (2018). Their pipeline first launches multiple process, preferably as many as available cores. Each these processes first downloads one file WET from the Common Crawl which then proceeds to decompress after the download is over. After decompressing, an instance of the fastText linear classifier (Joulin et al., 2016, 2017) is launched, the classifier processes each WET file line by line, generating a language tag for each line. The tags are then stored in a tag file which holds a one-toone correspondence between lines of the WET file and its corresponding language tag. The WET file and the tag files are read sequentially and each on the WET file line holding the condition of being longer that 100 bytes is appended to a language file containing only plain text (tags are discarded). Finally the tag file and the WET files are deleted.

Only when one of these processes finishes another can be launched. This means that one can at most process and download as many files as cores the machine has. That is, if for example a machine has 24 cores, only 24 WET files can be downloaded and processed simultaneously, moreover, the 25th file won't be downloaded until one of the previous 24 files is completely processed.

When all the WET files are classified, one would normally get around 160 language files, each file holding just plain text written in its corresponding language. These files still need to be filtered in order to get rid of all files containing invalid UTF-8 characters, so again a number of processes are launched, this time depending on the amount of memory of the machine. Each process reads a language file, first filters for invalid UTF-8 characters and then performs deduplication. A simple non-collision resistant hashing algorithm is used to deduplicate the files.

The fastText linear classifier works by representing sentences for classification as bags of words (BoW) and training a linear classifier. A weight matrix A is used as a look-up table over

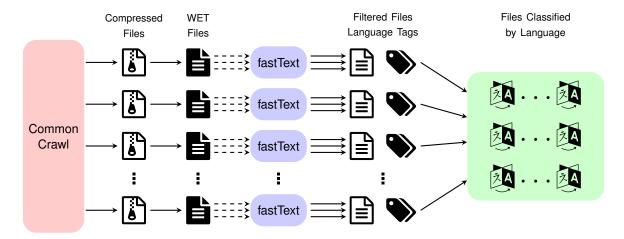

Figure 1: A scheme of the *goclassy* pipeline. The red square represents the Compressed WET files stored on Amazon Web Services. The licons represent the gzip files stored locally, the represent one of the 50K WET files. The represents the filtered file and the represents a file of language tags, one tag per line in licons. The represents one of the 166 classified files. Each arrow represents an asynchronous non blocking worker and dotted arrows represent a line filtering process.

the words, the word representations are then averaged into a text representation which is fed to the linear classifier. The architecture is in general similar to the cbow model of Mikolov et al. (2013) but the middle word is replaced by a label. They uses a softmax function f to compute the probability distribution over the classes. For a set of N documents, the model is trained to minimise the negative log-likelihood over the classes:

$$-\frac{1}{N}\sum_{n=1}^{N}y_n\log\left(f(BAx_n)\right),\,$$

where x_n is the normalized bag of features of the n-th document, y_n is the n-th label, and A, B are the weight matrices. The pre-trained fast-Text model for language recognition (Grave et al., 2018) is capable of recognising around 176 different languages and was trained using 400 million tokens from Wikipedia as well as sentences from the Tatoeba website 11 .

5 Asynchronous pipelines

We propose a new pipeline derived from the fast-Text one which we call goclassy, we reuse the fastText linear classifier (Joulin et al., 2016, 2017) and the pre-trained fastText model for language recognition (Grave et al., 2018), but we completely rewrite and parallelise their pipeline in an asynchronous manner.

The order of operations is more or less the same as in the fastText pre-processing pipeline but instead of clustering multiple operations into a single blocking process, we launch a worker for each operation, we bound the number of possible parallel operations at a given time by the number of available threads instead of the number of CPUs. We implement goclassy using the Go programming language¹² so we let the Go runtime¹³ handle the scheduling of the processes. Thus in our pipeline we don't have to wait for a whole WET file to download, decompress and classify in order to start downloading and processing the next one, a new file will start downloading and processing as soon as the scheduler is able to allocate a new process.

When using electromechanical mediums of storage, I/O blocking is one of the main problems one encounters; to overcome this, we introduced buffers in all our I/O operations, a feature that is not present in the fastText pre-processing pipeline. We also create, from the start, a file for each of the 176 languages that the pre-trained fastText language classifier is capable of recognising, and we always leave them open, as we find that getting a file descriptor to each time we want to write, if we wanted leave them open just when needed, introduces a big overhead.

We also do the filtering and cleaning processes at line level before feeding each line to the clas-

Table 1: Benchmarks are done using the UNIX time tool, are repeated 10 times each and are done for random samples of 10, 100 and 200 WET files. Only the classifying and filtering part are benchmarked. The table shows the minimum, maximum and mean time for the user, real and sys time over the 10 runs. Here "fastText" is used as short for the pipeline

sifier, this makes us create a new filtered file so that we can have a correspondence with the tag file, which in turn will consume more space, but that will also reduce the amount of unnecessary classifications performed by fastText. The filtered and file tags are then read and lines are appended to its corresponding language file. The writing in the classification step is asychronous, meaning that process writing a line to the filtered files does not wait for the classifier to write a tag on the tag file. Figure 1 shows the pipeline up to this point.

After all WET files are processed, we then use used Isaac Whitfield's deduplication tool runiq¹⁴ which is based on Yann Collet's xxhash64¹⁵, an extremely fast non-cryptographic hash algorithm that is resistant to collisions. We finally use the Mark Adler's pigz¹⁶ for data compression, as opposed to the canonical UNIX tools proposed in the original fastText pipeline. We add both tools to our concurrent pipeline, executing multiple instances of them in parallel, in order to ensure we use the most of our available resources at a given time.

Beyond improving the computational time required to classify this corpus, we propose a simple improvement on the cleaning scheme in the fast-Text pre-processing pipeline. This improvement allows our pipeline to better take into account the multilingual nature of Common Crawl; that is, we count UTF-8 characters instead of bytes for setting the lower admissible bound for the length of a line to be fed into the classifier. This straightforward modification on the fasttext pre-processing pipeline assures we take in account the multiple

languages present in Common Crawl that use non-ASCII encoded characters.

Given that our implementation is written in Go, we release binary distributions ¹⁷ of goclassy for all major operating systems. Both pigz and runiq are also available for all major operating systems.

6 Benchmarks

We test both pipelines against one another in an infrastructure using traditional electromechanical storage mediums that are connected to the main processing machine via an Ethernet interface, that is, a low I/O speed environment as compared to an infrastructure where one would have an array of SSDs connected directly to the main processing machine via a high speed interface.

Benchmarks of our pipeline show a dramatic improvement of processing time compared to the original fasttext preprocessing pipeline. We show that in our particular infrastructure, we are capable of reducing the processing time from several months to less than five days, to classify by language and clean the whole Common Crawl corpus. This significant reduction in computing time not only improves the usability of this particular corpus, but also substantially reduces the amount of energy consumption required to perform this particular task.

As we understand that even an infrastructure with more than 20TB of free space in traditional electromechanical storage is not available to everyone, we propose a second pipeline that actively deletes already processed data and that only uncompressed files when needed, thus ensuring that no more than 10TB of storage are used at a

¹⁴https://github.com/whitfin/runiq

¹⁵https://github.com/Cyan4973/xxHash

¹⁶https://zlib.net/pigz/

¹⁷https://github.com/pjox/goclassy

given time. We nevertheless note that introducing compression increases the amount of computation time, which is a trade-off that some users or researchers might make as it might be more suitable for their available infrastructure. In both cases we commit to open source, upon publication of this article, a full implementation of the two proposed pipelines so that our results can be more easily reproduced.

7 Open Super-large Crawled ALMAnaCH coRpus

Finally, we are aware that some researchers might not even have access to a big enough infrastructure to run or implement either of our pipelines, and that even if previously used and cited in NLP and ML research, there is currently no public distribution of Common Crawl which is filtered, classified by language and ready to use for Machine Learning applications. We will initially publish a processed version of the November 2018 copy of Common Crawl which is comprised of usable data in 166 different languages. We will also consider the possibility of future updates on the data as the Common Crawl corpus grows.

The Open Super-large Crawled ALMAnaCH¹⁸ coRpus (OSCAR¹⁹)

After processing all the data with of our proposed pipelines, the size of the whole corpus is reduced to 6.3TB, but in spite of this considerable reduction, our distribution of Common Crawl still dwarfs other more traditional large corpora as we can see in the following table

8 Conclusions

We are sure that our work will greatly benefit researchers working on an either constrain infrastructure or a low budget setting. We are also confident, that by publishing a classified version of Common Crawl, we will substantially increase the amount of available public data for medium to low resource languages, thus improving and facilitating NLP research for them. Furthermore, as our pipeline speeds-up and simplifies the treatment of Common Crawl, we believe that our contribution can be further parallelized and adapted to treat multiple snapshots of Common Crawl opening the door to what would be otherwise costly diachronic

studies of the use of a given language throughout the internet.

Finally, we note that both our proposed pipelines are data independent, which means that they can be reused to process, clean and classify any sort of big multilingual corpus that is available in plain text form and that is UTF-8 encoded; meaning that the impact of our work goes way beyond a single corpus.

Acknowledgments

The authors are grateful to Inria Paris "rioc" computation cluster for providing resources and support, and for allowing us to store the complete copies of both the raw and the filtered Common Crawl versions on their infrastructure.

Table 2: Size of the OSCAR corpus by language measured in bytes and number of words. Standard UNIX human-readable notation is used for the size in byte. We define "words" as spaced separated tokens, which gives a good estimate of the size of each corpus for languages using Latin or Cyrillic alphabets, but might give a misleading size for other languages such as Chineese or Japanese.
